Modern C++

Practical uses of C++17 features

```cpp
const char*
std::string
std::string_view
```

C-string vs `std::string`

The general recommendation is: use `std::string` and avoid using C raw string.

but...

C-string vs `std::string`

The general recommendation is: use `std::string` and avoid using C raw string.

but...

... sometimes you just can't

Interfacing with C API

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strcpy(ifr.ifr_name,ifname.cstr());
}
```

```cpp
struct ifreq {
    char ifr_name[IFNAMSIZ]; /* Interface name */
    /*...*/
};
```

Interfacing with C API

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strcpy(ifr.ifr_name,ifname.cstr());
}
```

```cpp
struct ifreq {
    char ifr_name[IFNAMSIZ]; /* Interface name */
    /*...*/
};
```

Who guarantees that ifname fits into the fixed-size `ifr_name` buffer?

Interfacing with C API

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strncpy(ifr.ifr_name,ifname.cstr(), sizeof(ifr.ifr_name));
}
```

Interfacing with C API

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strncpy(ifr.ifr_name,ifname.cstr(), sizeof(ifr.ifr_name));
}
```

Less bad but still wrong - buffer is not null-terminated.

Interfacing with C API

```
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strncpy(ifr.ifr name,ifname.cstr(), sizeof(ifr.ifr_name) - 1);
    ifr.ifrname[sizeof(ifr.irfname) – 1] = ’ \0 ’ ;
}
```

Interfacing with C API

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr ;
    strncpy(ifr.ifr name,ifname.cstr(), sizeof(ifr.ifr_name) - 1);
    ifr.ifrname[sizeof(ifr.irfname) – 1] = ’ \0 ’ ;
}
```

Correct but could be inefficient.

Safe string copy

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

- destination buffer is passed to the function and coping never reaches beyond it
- the null terminator is added at the end

Safe string copy

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

- destination buffer is passed to the function and coping never reaches beyond it
- the null terminator is added at the end

```cpp
void configureNetworkInterface(const std::string& ifname)
{
    ifreq ifr;
    safeStringCopy(ifname, ifr_ifr_name, sizeof(ifr.ifr_name));
}
```

Never use `strcpy` to copy a string which lengh is not known at compile time into a fixed size array.

Fixed size buffer copy

```c
const int SIZE = 20;

char s[SIZE];
strcpy(s, "Sometimes seems OK");
```

Fixed size buffer copy

```
const int SIZE = 20;

char s[SIZE];
strcpy(s, "Sometimes seems OK");
```

```
const int SIZE = 20;

char s[SIZE];
strcpy(s, "Sometimes seems NOT OK");
```

Fixed size buffer copy

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
const int SIZE = 20;

char s[SIZE];
safeStringCopy(std::string{"Sometimes seems NOT OK"}, s, sizeof(s));
```

Fixed size buffer copy

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
const int SIZE = 20;

char s[SIZE];
safeStringCopy(std::string{"Sometimes seems NOT OK"}, s, sizeof(s));
```

Unnecessary string allocation.

Fixed size buffer copy

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

Second overload taking `const char*`

Fixed size buffer copy

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

Second overload taking `const char*`

```cpp
const int SIZE = 20;

char s[SIZE];
safeStringCopy("Sometimes seems NOT OK", s, sizeof(s));
```

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

Implement the first function in terms of the second ?

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    return safeStringCopy(src.c_str(), dest, destLen);
}
```

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

Implement the first function in terms of the second ?

```cpp
size_t safeStringCopy(const std::string& src, char* dest, size_t destLen)
{
    return safeStringCopy(src.c_str(), dest, destLen);
}
```

```cpp
size_t safeStringCopy(const char* src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(strlen(src), destLen - 1);
    std::copy_n(src, len, dest);
    dest[len] = '\0';
    return len;
}
```

Efficiency issue: calculate length of `std::string`

std::string_view

```
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view& other) noexcept;
constexpr basic_string_view(const CharT* s, size_type count);
constexpr basic_string_view(const CharT* s);
```

- 'reference' to const character sequences
- provides `std::string`-like interface without owning the underlying memory

std::string_view

```
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view& other) noexcept;
constexpr basic_string_view(const CharT* s, size_type count);
constexpr basic_string_view(const CharT* s);
```

- 'reference' to const character sequences
- provides `std::string`-like interface without owning the underlying memory

```
std::string s = "Simple string";
std::string_view sv = s;
std::string_view sub_sv = sv.substr(0, 5); // sub_sv == "Simple"
```

std::string_view

```cpp
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view& other) noexcept;
constexpr basic_string_view(const CharT* s, size_type count);
constexpr basic_string_view(const CharT* s);
```

- 'reference' to const character sequences
- provides `std::string`-like interface without owning the underlying memory

```cpp
std::string s = "Simple string";
std::string_view sv = s;
std::string_view sub_sv = sv.substr(0, 5); // sub_sv == "Simple"
```

```cpp
const char* s = "Raw string";
std::string_view sv = s;
sv.remove_prefix(4);  // sv == "string";
```

```cpp
size_t safeStringCopy(std::string_view src, char* dest, size_t destLen)
{
    if (destLen == 0)
    {
        return 0;
    }
    auto len = std::min(src.length(), destLen - 1);
    std::copy_n(src.begin(), len, dest);
    dest[len] = '\0';
    return len;
}
```

Single function which serves both `std::string` and raw string

Prefer passing `std::string_view` to a function over `const std::string&`

C-string vs `std::string`

```cpp
class WithString
{
    std::string mName;
};

std::vector<WithString> withString;
```

```cpp
class WithCString
{
    char mName[20];
};

std::vector<WithCString> withCString;
```

C-string vs `std::string`

```cpp
class WithString
{
    std::string mName;
};

std::vector<WithString> withString;
```
```cpp
class WithCString
{
    char mName[20];
};

std::vector<WithCString> withCString;
```
What is more efficient?

std::find

std::sort

```cpp
class WithCString
{
    char mName[20];
public:
    const char* name() const {return mName;}
};
```

```
class WithCString
{
    char mName[20];
public:
    const char* name() const {return mName;}
};
```

Returns raw string forcing user to use raw string functions.

```cpp
class WithCString
{
    char mName[20];
public:
    std::string name() const {return std::string{mName, 20};}
};
```

```
class WithCString
{
    char mName[20];
public:
    std::string name() const {return std::string{mName, 20};}
};
```

Returns `std::string` but requires a new copy of the original string.

```cpp
class WithCString
{
    char mName[20];
public:
    std::string_view name() const {return std::string_view{mName, 20};}
};
```

```cpp
class WithCString
{
    char mName[20];
public:
    std::string_view name() const {return std::string_view{mName, 20};}
};
```

Returns `std::string_view`: no copy + nice string-like interface.

When a class keeps string data as char array the accessor member function should return `std::string_view` to that array.

Dangling `std::string_view`

```cpp
std::string_view sv;
{
    std::string s = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

Dangling `std::string_view`

```cpp
std::string_view sv;
{
    std::string s = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

```cpp
std::string_view sv = std::string{"some string"};
std::cout << sv << '\n';
```

Dangling `std::string_view`

```cpp
std::string_view sv;
{
    std::string s = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

```cpp
std::string_view sv = std::string{"some string"};
std::cout << sv << '\n';
```

```cpp
std::string_view sv;
{
    char s[] = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

Dangling `std::string_view`

```cpp
std::string_view sv;
{
    std::string s = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

```cpp
std::string_view sv = std::string{"some string"};
std::cout << sv << '\n';
```

```cpp
std::string_view sv;
{
    char s[] = "some string";
    sv = s;
}
std::cout << sv << '\n';
```

`std::string_view` is a non-owning reference to the underlying string. If the string is deleted the `string_view` dangles.

std::span<T> (C++20)

- an iterable view of the contiguous sequence of objects
- does not own the underlying memory

std::span<T> (C++20)

- an iterable view of the contiguous sequence of objects
- does not own the underlying memory

```cpp
std::vector<int> v = {1,2,3,4,5};
std::span<int> s(v);

std::span<int> sub_s = s.subspan(0,2); // {1,2,3}
```

```

```cpp
bool v1 = std::is_pointer<int>::value; // v1 == false
bool v2 = std::is_pointer<int*>::value; // v2 == true
```

```cpp
template <typename T>
constexpr bool is_pointer_v = std::is_pointer<T>::value;
```

std::integral_constant

```cpp
template <typename T, T v>
integral_constant
{
    static constexpr T value = v;
};
```

```cpp
using const_5 = std::integral_constant<int, 5>;
using const_6 = std::integral_constant<int, 6>;

std::cout << const_5::value << '\n'; // prints 5
std::cout << const_6::value << '\n'; // prints 6
```

```cpp
using true_type  = integral_constant<bool, true>;
using false_type = integral_constant<bool, false>;
```

```cpp
template <typename T>
struct is_pointer : false_type {};

template <typename T>
struct is_pointer<T*> : true_type {};
```

```cpp
bool v1 = std::is_pointer<int>::value; // v1 == false
bool v2 = std::is_pointer<int*>::value; // v2 == true
```

```cpp
template <typename T>
constexpr bool is_pointer_v = std::is_pointer<T>::value;
```

```cpp
bool v1 = std::is_pointer_v<int>;  // v1 == false
bool v2 = std::is_pointer_v<int*>; // v2 == true
```

decltype

<type_traits>

std::integral_constant

std::forward

```cpp
class Foo
{
public:
    Foo() = default;

    Foo(const Foo& other) { std::cout << "Copy Foo\n"; }

    Foo(Foo&& other) { std::cout << "Move Foo\n"; }
};

class Bar

```

```
Move Foo

Copy Foo
```

```
Copy Foo

Copy Foo
```

Where does the extra copy come from?

Forwarding reference

There are special template type deduction rules for a function taking a *forwarding reference*:

```
template <typename T>
void func(T&& value);
```

Forwarding reference

There are special template type deduction rules for a function taking a *forwarding reference*:

```
template <typename T>
void func(T&& value);
```

- When called with *l-value* of type Foo T is deduced to Foo&

```
Foo foo;
func(foo); // T == Foo&
```

```
void func(Foo& && value);
// As per reference collapsing rules this becomes:
void func(Foo& value);
```

Forwarding reference

There are special template type deduction rules for a function taking a *forwarding reference*:

```
template <typename T>
void func(T&& value);
```

- When called with *l-value* of type `Foo` T is deduced to `Foo&`

```
Foo foo;
func(foo); // T == Foo&
```

```
void func(Foo& && value);
// As per reference collapsing rules this becomes:
void func(Foo& value);
```

- When called with *r-value* of type `Foo` T is deduced to `Foo`

```
func(Foo{}); // T == Foo
```

```
void func(Foo&& value);
```

Forwarding reference

```cpp
void doFoo(const Foo&);
void doFoo(Foo&&);

template <typename T>
void func(T&& value)
{
    doFoo(value);
}
```

```cpp
Foo foo;
func(foo);    // doFoo(const Foo&) is called

func(Foo{}); // doFoo(const Foo&) is called
```

Forwarding reference

```cpp
void doFoo(const Foo&);
void doFoo(Foo&&);

template <typename T>
void func(T&& value)
{
    doFoo(value);
}
```

```cpp
Foo foo;
func(foo);    // doFoo(const Foo&) is called

func(Foo{}); // doFoo(const Foo&) is called
```

```cpp
void doFoo(const Foo&);
void doFoo(Foo&&);

template <typename T>
void func(T&& value)
{
    doFoo(std::forward<T>(value));
}
```

```cpp
Foo foo;
func(foo);    // doFoo(const Foo&) is called

func(Foo{}); // doFoo(Foo&&) is called
```

Forwarding reference

```
void doFoo(const Foo&);
void doFoo(Foo&&);

template <typename T>
void func(T&& value)
{
    doFoo(value);
}
```

```
Foo foo;
func(foo);    // doFoo(const Foo&) is called

func(Foo{});  // doFoo(const Foo&) is called
```

```
void doFoo(const Foo&);
void doFoo(Foo&&);

template <typename T>
void func(T&& value)
{
    doFoo(std::forward<T>(value));
}
```

```
Foo foo;
func(foo);    // doFoo(const Foo&) is called

func(Foo{});  // doFoo(Foo&&) is called
```

Perfect forwarding

```cpp
class Foo
{
public:
    Foo() = default;

    Foo(const Foo& other) { std::cout << "Copy Foo\n"; }

    Foo(Foo&& other) { std::cout << "Move Foo\n"; }
};

class Bar
{
    Foo foo;
public:
    Bar(const Foo& f) : foo(f) {}
    Bar(Foo&& f) : foo(std::move(f)) {}
};
```

```cpp
template<typename T, typename... Args>
unique_ptr<T> make_unique(Args&&... args)
{
    return std::unique_ptr<T>(new T{args...});
}
```

```cpp
unique_ptr<Bar> bar1{new Bar{Foo{}}}; // r-value reference

Foo foo;
unique_ptr<Bar> bar2{new Bar{foo}}; // l-value reference
```

```cpp
auto bar1 = make_unique<Bar>(Foo{}); // r-value reference

Foo foo;
auto bar2 = make_unique<Bar>(foo); // l-value reference
```

```
Move Foo

Copy Foo
```

```
Copy Foo

Copy Foo
```

```cpp
class Foo
{
public:
    Foo() = default;

    Foo(const Foo& other) { std::cout << "Copy Foo\n"; }

    Foo(Foo&& other) { std::cout << "Move Foo\n"; }
};

class Bar
{
    Foo foo;
public:
    Bar(const Foo& f) : foo(f) {}
    Bar(Foo&& f) : foo(std::move(f)) {}
};
```

```cpp
template<typename T, typename... Args>
unique_ptr<T> make_unique(Args&&... args)
{
    return std::unique_ptr<T>(new T{std::forward<Args>(args)...});
}
```

```cpp
unique_ptr<Bar> bar1{new Bar{Foo{}}}; // r-value reference

Foo foo;
unique_ptr<Bar> bar2{new Bar{foo}}; // l-value reference
```

```cpp
auto bar1 = make_unique<Bar>(Foo{}); // r-value reference

Foo foo;
auto bar2 = make_unique<Bar>(foo); // l-value reference
```

```
Move Foo

Copy Foo
```

```
Move Foo

Copy Foo
```

std::optional<T>

std::optional<T>

- container which can be empty or hold a single value of type T

std::optional<T>

- container which can be empty or hold a single value of type T

- has pointer-like interface

  - operator *
  - operator ->

std::optional<T>

- container which can be empty or hold a single value of type T

- has pointer-like interface

  - `operator *`
  - `operator ->`

- no heap allocation

std::optional<T>

- container which can be empty or hold a single value of type T

- has pointer-like interface

  - `operator *`
  - `operator ->`

- no heap allocation

- based on the *Monad* concept in functional programming languages
  - Haskell `Maybe` monad

std::optional<T>

```cpp
std::optional<int> empty = std::nullopt;
EXPECT_FALSE(empty.has_value());
EXPECT_THROW(empty.value(), std::bad_optional_access);
EXPECT_EQ(10, empty.value_or(10));
int x = *empty; // undefined behavior

std::optional<int> value = 123;
EXPECT_TRUE(value.has_value());
EXPECT_EQ(123, value.value());
EXPECT_EQ(123, value.value_or(10));
EXPECT_EQ(123, *value);
```

std::optional<T>

```cpp

```cpp
std::optional<int> empty = std::nullopt;
EXPECT_FALSE(empty.has_value());
EXPECT_THROW(empty.value(), std::bad_optional_access);
EXPECT_EQ(10, empty.value_or(10));
int x = *empty; // undefined behavior

std::optional<int> value = 123;
EXPECT_TRUE(value.has_value());
EXPECT_EQ(123, value.value());
EXPECT_EQ(123, value.value_or(10));
EXPECT_EQ(123, *value);
```

std::optional<T>

in-place construction

```cpp
struct Foo
{
    Foo(std::string s, int i);
};
```

```cpp
std::optional<Foo> opt{std::in_place, "Foo", 10};
```

std::optional<T>

in-place construction

```cpp
struct Foo
{
    Foo(std::string s, int i);
};
```

```cpp
std::optional<Foo> opt{std::in_place, "Foo", 10};
auto opt2 = std::make_optional<Foo>("Foo, 10");
EXPECT_EQ(*opt1, *opt2);
```

std::optional<T>

in-place construction

```
struct Foo
{
    Foo(std::string s, int i);
};
```

```
std::optional<Foo> opt{std::in_place, "Foo", 10};
auto opt2 = std::make_optional<Foo>("Foo, 10");
EXPECT_EQ(*opt1, *opt2);
```

```
template <typename T, typename... Args>
std::optional<T> make_optional(Args&&... args)
{
    return std::optional<T>(std::in_place, std::forward<Args>(args)...);
}
```

std::optional<T>

in-place construction

```cpp
struct Foo
{
    Foo(std::string s, int i);
};
```

```cpp
std::optional<Foo> opt{std::in_place, "Foo", 10};
auto opt2 = std::make_optional<Foo>("Foo, 10");
EXPECT_EQ(*opt1, *opt2);
```

```cpp
template <typename T, typename... Args>
std::optional<T> make_optional(Args&&... args)
{
    return std::optional<T>(std::in_place, std::forward<Args>(args)...);
}
```

Infamous atoi

```cpp
int atoi(const char *str);
```

```cpp
auto x1 = atoi("123"); // x1 = 123
auto x3 = atoi("123xxx"); // x3 = 123;
auto x2 = atoi("0"); // x2 = 0
auto x4 = atoi("xxx123"); // x4 = 0
auto x5 = atoi(nullptr); // undefined behavior
```

Infamous `atoi`

```cpp
int atoi(const char *str);
```

```cpp
auto x1 = atoi("123"); // x1 = 123
auto x3 = atoi("123xxx"); // x3 = 123;
auto x2 = atoi("0"); // x2 = 0
auto x4 = atoi("xxx123"); // x4 = 0
auto x5 = atoi(nullptr); // undefined behavior
```

0 return value is ambigous.

What's the best way of returning parsing status along with the converted number?

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
int x = 0;
if (my_atoi(str, x))
{
    //...
}
```

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
int x = 0;
if (my_atoi(str, x))
{
    //...
}
```

Declaring x before it can be assigned in the function.

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
int x;
if (my_atoi(str, x))
{
    //...
}

int y = x;
```

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
int x;
if (my_atoi(str, x))
{
    //...
}

int y = x;
```

Common mistake: using unitialized value

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
if (int x = 0; my_atoi(str, x))
{
    //...
}
```

C++17 feature: initializer in `if statement` may be handy

status as return value, result as output argument

```cpp
bool my_atoi(const char* str, int& val)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return false;
    }
    val = atoi(str);
    return val;
}
```

```cpp
if (int x = 0; my_atoi(str, x))
{
    //...
}
```

C++17 feature: initializer in `if statement` may be handy

result as return value, status as output argument

```cpp
int my_atoi(const char* str, bool& ok)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        ok = false;
        return 0;
    }
    ok = true;
    return atoi(str);
}
```

```cpp
bool ok = false;
int x = my_atoi(str, ok);
if (ok)
{
    //...
}
```

result as return value, status as output argument

```cpp
int my_atoi(const char* str, bool& ok)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        ok = false;
        return 0;
    }
    ok = true;
    return atoi(str);
}
```

```cpp
bool ok = false;
int x = my_atoi(str, ok);
if (ok)
{
    //...
}
```

Declaring ok before it can be initialized with the function output.

result as return value, status as output argument

```cpp
int my_atoi(const char* str, bool& ok)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        ok = false;
        return 0;
    }
    ok = true;
    return atoi(str);
}
```

```cpp
bool ok = false;
if (int x = my_atoi(ok); ok)
{
    //...
}
```

Use of `if statement` initializer

result as return value, status as output argument

```cpp
int my_atoi(const char* str, bool& ok)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        ok = false;
        return 0;
    }
    ok = true;
    return atoi(str);
}
```

```cpp
bool ok = false;
if (int x = my_atoi(ok); ok)
{
    //...
}
```

Use of `if statement` initializer

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
auto ret = my_atoi(str);
if (ret.first)
{
    int x = ret.second;
}
```

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
auto ret = my_atoi(str);
if (ret.first)
{
    int x = ret.second;
}
```

Need to remember what is first and what is second.

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
if (auto ret = my_atoi(str); ret.first)
{
    int x = ret.second;
}
```

Use of `if statement` initializer

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
auto [valid, value] = my_atoi(str);
if (valid)
{
    int x = value;
}
```

C++17 structured binding

Structured binding

```cpp
struct Foo
{
    int i;
    std::string s;
    double d;
};

Foo makeFoo(int i, std::string s, double d)
{
    return Foo{i, std::move(s), d};
}
```

```cpp
Foo foo = makeFoo(10, "foo", 0.5);
auto i = foo.i;
auto s = foo.s;
auto d = foo.d;
```

- "traditional" way of "unpacking" a struct

Structured binding

```cpp
struct Foo
{
    int i;
    std::string s;
    double d;
};

Foo makeFoo(int i, std::string s, double d)
{
    return Foo{i, std::move(s), d};
}
```

```cpp
auto [i,s,d] = makeFoo(10, "foo", 0.5);
```

- structured binding directly assigning members of Foo to variables `i, s, d`

Structured binding

```cpp
struct Foo
{
    int i;
    std::string s;
    double d;
};

Foo makeFoo(int i, std::string s, double d)
{
    return Foo{i, std::move(s), d};
}
```

```cpp
Foo foo = makeFoo(10, "foo", 0.5);
auto& [i,s,d] = foo;
```

- structured binding assigning references to members of Foo

Structured binding

```cpp
struct Foo
{
    int i;
    std::string s;
    double d;
};

Foo makeFoo(int i, std::string s, double d)
{
    return Foo{i, std::move(s), d};
}
```

```cpp
auto& [i,s,d] = makeFoo(10, "foo", 0.5);
```

- compiler error: cannot assign temporary variable to non-cost l-value reference

Structured binding

```cpp
struct Foo
{
    int i;
    std::string s;
    double d;
};

Foo makeFoo(int i, std::string s, double d)
{
    return Foo{i, std::move(s), d};
}
```

```cpp
const auto& [i,s,d] = makeFoo(10, "foo", 0.5);
```

- Okay: const reference extend the lifetime of the temporary

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
auto [valid, value] = my_atoi(str);
if (valid)
{
    int x = value;
}
```

C++17 structured binding

result & status as return value (`std::pair`)

```cpp
std::pair<bool, int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return {false, 0};
    }
    return {true, atoi(str)};
}
```

```cpp
if (auto [valid, value] = my_atoi(str); valid)
{
    int x = value;
}
```

C++17 structured binding with `if statement` initializer

result & status as return value (`std::optional`)

```cpp
std::optional<int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return std::nullopt;
    }
    return atoi(str);
}
```

result & status as return value (`std::optional`)

```cpp
std::optional<int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return std::nullopt;
    }
    return atoi(str);
}
```

```cpp
if (auto v = my_atoi(str); v)
{
    auto value = *v;
}
```

result & status as return value (`std::optional`)

```cpp
std::optional<int> my_atoi(const char* str)
{
    if (str == nullptr || !std::isdigit(str[0]) || !str[0] != '-')
    {
        return std::nullopt;
    }
    return atoi(str);
}
```

```cpp
if (auto v = my_atoi(str); v)
{
    auto value = *v;
}
```

```cpp
auto x1 = my_atoi("123"); // *x1 = 123
auto x3 = my_atoi("123xxx"); // *x3 = 123;
auto x2 = my_atoi("0"); // *x2 = 0
auto x4 = my_atoi("xxx123"); // x4 = nullopt
auto x5 = my_atoi(nullptr); // x5 = nullopt
```

```cpp
int main(int argc, const char* argv[])
{
    auto x = my_atoi(argv[1]);
    if (!x)
    {
        std::cerr << "Number expected\n";
        return -1;
    }
    std::cout << x.value() << '\n';
}
```

std::optional comes handy when parsing command line or files

```cpp
bool my_atoi(const char* s, int& i);

int my_atoi(const char* s, bool& valid);

std::pair<bool, int> my_atoi(const char* s);

std::optional<int> my_atoi(const char* s);
```

Use `std::optional<T>` as a return type as an alternative to throwing exception when correct value cannot be returned.

Optional data members

```json
"parameters" : [
{
    "name"   : "temperature",
    "access" : "read-only",
    "type"   : "integer"
},
{
    "name"   : "power",
    "access" : "read-only",
    "type"   : "integer",
    "range"  : {"min": -10, "max": 10}
}
]
```

```cpp
struct Parameter
{
    std::string name;
    Access access;
    Type type;
    // range ?
};
```

Optional data members

```json
"parameters" : [

    "range"   : {"min": -10, "max": 10}
}
]
```

```cpp
struct Parameter
{
    std::string name;
    Access access;
    Type type;
    std::optional<std::pair<int, int>> range;
};
```

Optional data members

```json
"parameters" : [
{
    "name"   : "temperature",
    "access" : "read-only",
    "type"   : "integer"
},
{
    "name"   : "power",
    "access" : "read-only",
    "type"   : "integer",
    "range"  : {"min": -10, "max": 10}
}
]
```

```cpp
struct Parameter
{
    std::string name;
    Access access;
    Type type;
    std::optional<std::pair<int, int>> range;
};

void print(const Parameter& p)
{
    std::cout << "name=" << p.name << '\n';
    std::cout << "access=" << p.access << '\n';
    std::cout << "type=" << p.type << '\n';
    if (auto range = p.range; range)
        std::cout << "range=" << range->first << ","  << range.second << '\n';
}
```

std::optional<T>

"Monadic" interface

Many times we pass a result of a function to another function:

```cpp
Shape makeShape(std::vector<Points> points);

Figure makeFigure(Shape shape);

Painting paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
Shape shape = makeShape({{1,2}, {3,3}, {1,0}});
Figure figure = makeFigure(shape);
Painting painting = paint(figure);
display(painting);
```

std::optional<T>

"Monadic" interface

Many times we pass a result of a function to another function:

```cpp
Shape makeShape(std::vector<Points> points);

Figure makeFigure(Shape shape);

Painting paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
display(paint(makeFigure(makeShape({{1,2}, {3,3}, {1,0}})))));
```

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
auto shape = makeShape({{1,2}, {3,3}, {1,0}});
if (shape)
{
    auto figure = makeFigure(*shape);
    if(figure)
    {
        auto painting = paint(*figure);
        if (painting)
        {
            display(painting);
        }
    }
}
```

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
auto shape = makeShape({{1,2}, {3,3}, {1,0}});
if (shape)
{
    auto figure = makeFigure(*shape);
    if(figure)
    {
        auto painting = paint(*figure);
        if (painting)
        {
            display(painting);
        }
    }

}
```

"Noisy code" due to error checking.

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
auto shape = makeShape({{1,2}, {3,3}, {1,0}});

if (!shape)
{
    return;
}

auto figure = makeFigure(*shape);

if(!figure)
{
    return;
}

auto painting = paint(*figure);
if (!painting)
{
    return;
}

display(*painting);
```

"Noisy code" due to error checking.

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

void display(const Painting& painting);
```

```cpp
auto shape    = makeShape({{1,2}, {3,3}, {1,0}});
auto figure   = bind(shape, makeFigure);
auto painting = bind(figure, paint);

if (painting)
{
    display(*painting);
}
```

```cpp
std::optional<Shape> makeShape(std::vector<Points> points);

std::optional<Figure> makeFigure(Shape shape);

std::optional<Painting> paint(const Figure& figure);

```

```cpp
auto shape    = makeShape({{1,2}, {3,3}, {1,0}});
auto figure   = bind(shape, makeFigure);
auto painting = bind(figure, paint);

if (painting)
{
    display(*painting);
}
```

What does the function `bind` do ?

```cpp
template <typename T, typename F>
auto bind(const std::optional<T>& opt, F&& f) -> std::invoke_result_t<F, T>
{
    if (opt.has_value())
    {
        return f(*opt);
    }
    return std::nullopt;
}
```

```cpp
template <typename T, typename F>
auto bind(const std::optional<T>& opt, F&& f) -> std::invoke_result_t<F, T>
{
    if (opt.has_value())
    {
        return f(*opt);
    }
    return std::nullopt;
}
```

```cpp
auto shape = makeShape({{1,2}, {3,3}, {1,0}});
auto figure = bind(shape, makeFigure);
auto painting = bind(figure, paint);
```

```cpp
template <typename T, typename F>
auto bind(const std::optional<T>& opt, F&& f) -> std::invoke_result_t<F, T>
{
    if (opt.has_value())
    {
        return f(*opt);
    }
    return std::nullopt;
}
```

```cpp
auto shape = makeShape({{1,2}, {3,3}, {1,0}});
auto figure = bind(shape, makeFigure);
auto painting = bind(figure, paint);
```

    }
};
```

std::any

std::any

- single value container
- type safe: keeps type information
- can hold an arbitrary type
- implementations should use Small Buffer Optimization technique to avoid heap allocation for small types

std::any

- single value container
- type safe: keeps type information
- can hold an arbitrary type
- implementations should use Small Buffer Optimization technique to avoid heap allocation for small types

Essentially, `std::any` is a type-safe replacement of `void*`

```cpp
std::any a1 = 123;

EXPECT_EQ(a1, a3);
```

Example: Database record

```cpp
struct DatabaseRecord
{
    std::string name;
    std::chrono::time_point lastModified;
    /* some generic schema */

    void* userData = nulltpr;
};
```

```cpp
std::vector<DatabaseRecord> database;

DatabaseRecord record;
record.name "rec1"

record.userData = new Foo{};
```

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Foo* foo = static_cast<Foo*>(it->userData);
foo.doFoo();
```

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Bar* bar = static_cast<Bar*>(it->userData);
bar.doBar(); // undefined behavior
```

Type **un**safe

Example: Database record

```cpp
struct DatabaseRecord
{
    std::string name;
    std::chrono::time_point lastModified;
    /* some generic schema */

    void* userData = nulltpr;
};
```

```cpp
struct DatabaseRecord
{
    std::string name;
    std::chrono::time_point lastModified;
    /* some generic schema */

    std::any userData;
};
```

```cpp
std::vector<DatabaseRecord> database;

DatabaseRecord record;
record.name "rec1"

record.userData = new Foo{};
```

```cpp
std::vector<DatabaseRecord> database;

DatabaseRecord record;
record.name "rec1"

record.userData = Foo{};
```

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Foo* foo = static_cast<Foo*>(it->userData);
foo.doFoo();
```

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Foo* foo = std::any_cast<Foo*>(it->userData);
if (foo)
    foo.doFoo();
else
    // error
```

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Bar* bar = static_cast<Bar*>(it->userData);
bar.doBar(); // undefined behavior
```

Type **un**safe

```cpp
auto it = std::find(database.begin(), database.end(), "rec1");
Bar* bar = std::any_cast<Bar*>(it->userData);
if (bar)
    bar.doBar();
else
    // error
```

Type safe

`std::any`

Small Buffer Optimization

- All known Standard Library implementations employ Small Buffer Optimization technique
- For 'small objects' objects stored in side `std::any` there's no heap allocation
- What 'small object' is depends on the implementation e.g.:
  - GCC: 8 bytes or less
  - Clang: 24 bytes or less

Small Buffer Optimization

```cpp
struct Large
{
    Large() { std::cout << "Constructing Large\n"; }

    void* operator new(size_t s)
    {
        std::cout << "Allocating Large\n";
        return ::operator new(s);
    }

    char b[100];
};

int main()
{
    std::any a{Large{}};
}
```

```
Constructing Large
Allocating Large
```

Small Buffer Optimization

```cpp
struct Large
{
    Large() { std::cout << "Constructing Large\n"; }

    void* operator new(size_t s)
    {
        std::cout << "Allocating Large\n";
        return ::operator new(s);
    }

    char b[100];
};

int main()
{
    std::any a{Large{}};
}
```

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

```
Constructing Large
Allocating Large
```

```
Constructing Small
```

How it works?

```cpp
class any
{
public:
    any() {/*...*/}

    any(const any& other) {/*...*/}

    any(any&& other) noexcept {/*...*/}

    template <typename T>
    any(T&& value)
    {
        TypeHandler<T>::create(*this, std::forward<T>(value));
    }

    ~any() {/*...*/}

    void reset() {/*...*/}

    const std::type_info& type() const {/*...*/}

    // Rest of methods and operators...

private:
    void* mStorage = nullptr;

    static void move(any& _this, any& _dest){/*...*/ }
    static void* get(any& _this, const std::type_info& _info) {/*...*/ }
    static void* typeInfo() {/*...*/ }
};
```

Constructing object in the existing buffer using placement new

```cpp
template <typename T>
struct LargeTypeHandler
{
    static void* handle(Action act, any const * _this, any * other,
                        type_info const * info, const void* fallback_info)
    { /*...*/ }

    template <typename... Args>
    static T& create(any& dest, Args&&... args) {/*...*/ }
    static void destroy(any& _this)
    {
        delete static_cast<T*>(_this.mStorage.ptr);
        _this.mHandler = nullptr;
    }
    static void copy(any const& _this, any& _dest){/*...*/ }
    static void move(any& _this, any& _dest){/*...*/ }
    static void* get(any& _this, const std::type_info& _info) {/*...*/ }
    static void* typeInfo() {/*...*/ }
};
```

Releasing allocated heap memory

```cpp
template <typename T>
struct SmallTypeHandler
{
    static void* handle(Action act, any const * _this, any * other,
                        type_info const * info, const void* fallback_info)
    { /*...*/ }

    template <typename... Args>
    static T& create(any& dest, Args&&... args) {/*...*/ }
    static void destroy(any& _this)
    {
        T& value = *static_cast<T*>(
            static_cast<void*>(&_this.mStorage.buffer));
        value.~_Tp();
        _this.mHandler = nullptr;
    }
    static void copy(any const& _this, any& _dest){/*...*/ }
    static void move(any& _this, any& _dest){/*...*/ }
    static void* get(any& _this, const std::type_info& _info) {/*...*/ }
    static void* typeInfo() {/*...*/ }
};
```

Just calling the desctructor

```cpp
template <typename T>
struct LargeTypeHandler
{
    static void* handle(Action act, any const * _this, any * other,
                        type_info const * info, const void* fallback_info)
    { /*...*/ }

    template <typename... Args>
    static T& create(any& dest, Args&&... args) {/*...*/ }
    static void destroy(any& _this) {/*...*/ }
    static void copy(any const& _this, any& _dest)
    {
        create(dest, static_cast<const T&>(*_this.mStorage.ptr);
    }
    static void move(any& _this, any& _dest)
    {
        dest.mStorage = _this.mStorage
        dest.mHandler = &LargeTypeHandler::handle;
        _this.mHandler = nullptr;
    }
    static void* get(any& _this, const std::type_info& _info) {/*...*/ }
    static void* typeInfo() {/*...*/ }
};
```

```cpp
template <typename T>
struct SmallTypeHandler
{
    static void* handle(Action act, any const * _this, any * other,
                        type_info const * info, const void* fallback_info)
    { /*...*/ }

    template <typename... Args>
    static T& create(any& dest, Args&&... args) {/*...*/ }
    static void destroy(any& _this) {/*...*/ }
    static void copy(any const& _this, any& _dest)
    {
        create(dest, static_cast<const T&>(
            *static_cast<void const *>(&_this.mStorage.buffer)));
    }
    static void move(any& _this, any& _dest)
    {
        create(dest, std::move(
            static_cast<T&>(*static_cast<void*>(&_this.mStorage.buffer))));
        destroy(_this);
    }
    static void* get(any& _this, const std::type_info& _info) {/*...*/ }
    static void* typeInfo() {/*...*/ }
};
```

```cpp
class any
{
public:
    /*...*/

    template <typename T>
    any(T&& value)
    {
        using HandlerType = std::condtional_t<sizeof(T) <= sizeof(void*),
                                              SmallTypeHandler<T>,
                                              LargeTypeHandler<T>>;
        HandlerType::create(*this, std::forward<T>(value));
    }

private:
    union Storage
    {
        void* ptr = nullptr;
        std::array<std::byte, sizeof(void*)> buffer;
    }
    Storage mStorage;

    /* Type information */
    using HandleFuncPtr =  void* (*)(Action, any const *,
                                     any *, const std::type_info *,
                                     const void*fallback_info);
    HandlerFuncPtr mHandler = nullptr;
```

- Static buffer implementation is selected if `sizeof(T) <= sizeof(void*)`
- Dynamic heap allocation is selected otherwise

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

```
Constructing Small
```

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    Small(const Small& other) = default;

    Small(Small&& other) {b[0] = other.b[0];}

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    Small(const Small& other) = default;

    Small(Small&& other) {b[0] = other.b[0];}

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

```
Constructing Small
Allocating Small
```

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    Small(const Small& other) = default;

    Small(Small&& other) {b[0] = other.b[0];}

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

> Implementations are encouraged to avoid dynamic allocations for small objects, but such an optimization may only be applied to types for which std::is_nothrow_move_constructible returns true.

https://en.cppreference.com/w/cpp/utility/any

```
Constructing Small
Allocating Small
```

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    Small(const Small& other) = default;

    Small(Small&& other) noexcept {b[0] = other.b[0];}

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

noexcept keyword insures that the function does not throw.

Small Buffer Optimization

```cpp
struct Small
{
    Small() { std::cout << "Constructing Small\n"; }

    Small(const Small& other) = default;

    Small(Small&& other) noexcept {b[0] = other.b[0];}

    void* operator new(size_t s)
    {
        std::cout << "Allocating Small\n";
        return ::operator new(s);
    }

    char b[1];
};

int main()
{
    std::any a{Small{}};
}
```

noexcept keyword insures that the function does not throw.

```
Constructing Small
```

```cpp
class any
{
public:
    any(any&& other) noexcept {/*...*/}
};
```

- move constructor of `std::any` must gurantee not to throw
- if type's T move constructror may throw `std::any` cannot call it not to violate the noexcept gurantee
- in such case it will resort to heap allocation even for small types

```cpp
class any
{
public:
    /*...*/

    template <typename T>
    any(T&& value)
    {
        using HandlerType = std::condtional_t<sizeof(T) <= sizeof(void*) &&
                                              std::is_nothrow_move_constructible_t<T>,
                                              SmallTypeHandler<T>,
                                              LargeTypeHandler<T>>;
        HandlerType::create(*this, std::forward<T>(value));
    }

private:
    /*...*/
};
```

... but why is `std::any` move constructor `noexcept` in the first place ?

```cpp
struct Buffer
{
    Buffer(size_t s) : data{new int[s]}, size{s} {}

    Buffer(const Buffer& other)
    {
        data.reset(new int[other.size]);
        size = other.size;
        std::copy(other.data.get(), other.data.get() + other.size,
                  data.get());
    }

    Buffer(Buffer&& other)
    {
        data.swap(other.data);
        size = other.size;
    }

    std::unique_ptr<int[]> data;
    size_t size;
};
```

```cpp
std::vector<Buffer> vec;
vec.reserve(10);
for (auto i = 1; i <= 15; i++)
{
    vec.push_back(Buffer{100000000});
}
```

```cpp
struct Buffer
{
    Buffer(size_t s) : data{new int[s]}, size{s} {}

    Buffer(const Buffer& other)
    {
        data.reset(new int[other.size]);
        size = other.size;
        std::copy(other.data.get(), other.data.get() + other.size,
                  data.get());
    }

    Buffer(Buffer&& other)
    {
        data.swap(other.data);
        size = other.size;
    }

    std::unique_ptr<int[]> data;
    size_t size;
};
```

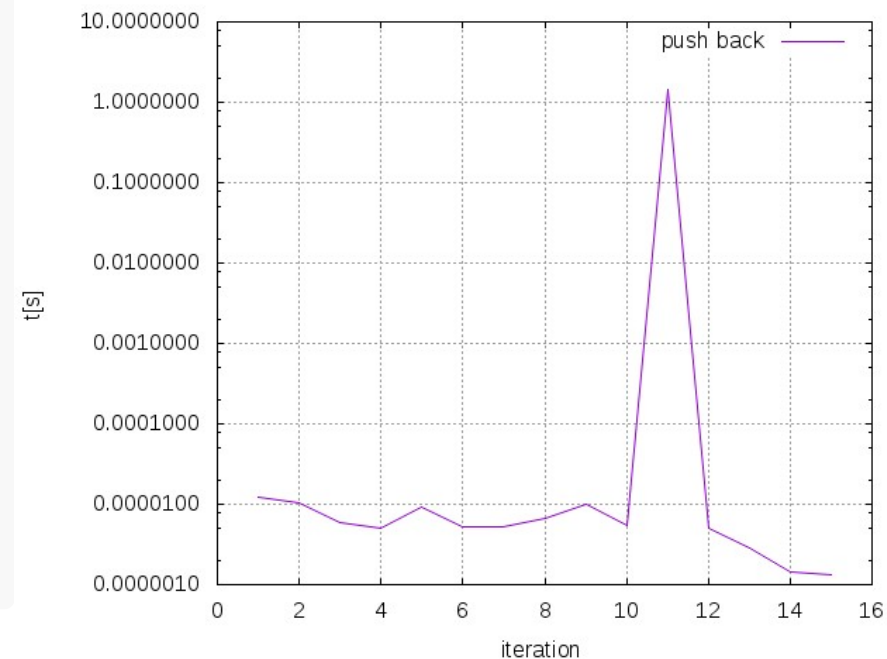

```cpp
std::vector<Buffer> vec;
vec.reserve(10);
for (auto i = 1; i <= 15; i++)
{
    vec.push_back(Buffer{100000000});
}
```
Strong Exception Guarantee

During re-allocation `std::vector` uses `move_if_no_except` function to move elements from the old to the new memory location. If the move constructor has no noexcept qualifier it will resort to copy.

Strong Exception Guarantee

- The Standard requires that the `std::vector`'s' re-allocating operations (e.g. `push_back`) must meet the Strong Exception Guarantee
- Should an exception is thrown during re-allocation the state of the `vector` from before the operation must be restored

Strong Exception Guarantee

- The Standard requires that the `std::vector's'` re-allocating operations (e.g. `push_back`) must meet the Strong Exception Guarantee
- Should an exception is thrown during re-allocation the state of the `vector` from before the operation must be restored

- The source location remains intact until the last element is copied
- In case of exception the `vector` simply discards the destination region and keeps the source region
Strong Exception Guarantee

- The Standard requires that the `std::vector's'` re-allocating operations (e.g. `push_back`) must meet the Strong Exception Guarantee
- Should an exception is thrown during re-allocation the state of the `vector` from before the operation must be restored

- The source location remains intact until the last element is copied
- In case of exception the `vector` simply discards the destination region and keeps the source region
- The source location remains intact until the last element is copied
- In case of exception the `vector` simply discards the destination region and keeps the source region

`std::vector` will use move during relocation only if type's T move constructor guarantees not to throw.

```cpp
struct Buffer
{
    Buffer(size_t s) : data{new int[s]}, size{s} {}

    Buffer(const Buffer& other)
    {
        data.reset(new int[other.size]);
        size = other.size;
        std::copy(other.data.get(), other.data.get() + other.size,
                  data.get());
    }

    Buffer(Buffer&& other) noexcept
    {
        data.swap(other.data);
        size = other.size;
    }

    std::unique_ptr<int[]> data;
    size_t size;
};
```

```cpp
std::vector<Buffer> vec;
vec.reserve(10);
for (auto i = 1; i <= 15; i++)
{
    vec.push_back(Buffer{100000000});
}
```

```cpp
struct Buffer
{
    Buffer(size_t s) : data{new int[s]}, size{s} {}

    Buffer(const Buffer& other)
    {
        data.reset(new int[other.size]);
        size = other.size;
        std::copy(other.data.get(), other.data.get() + other.size,
                  data.get());
    }

    Buffer(Buffer&& other) noexcept
    {
        data.swap(other.data);
        size = other.size;
    }

    std::unique_ptr<int[]> data;
    size_t size;
};
```

```cpp
std::vector<Buffer> vec;
vec.reserve(10);
for (auto i = 1; i <= 15; i++)
{
    vec.push_back(Buffer{100000000});
}
```

If move constructor is **not** `noexcept` operations on re-allocating containers may become expensive.

Class template parameter deduction

Function template type deduction has existed as long as the templates.

```cpp
template <typename T>
void f(const T& t);

f(10); // T is deduced to int
```

Function template type deduction has existed as long as the templates.

```cpp
template <typename T>
void f(const T& t);

f(10); // T is deduced to int
```

C++17 introduces class template type deduction

```cpp
template <typename T>
class Foo
{
public:
    Foo(const T& t);
};

Foo foo(10);
```

```cpp
std::pair p{1,2}; //compiler error in C++14
```

```cpp
std::pair p{1,2}; //compiler error in C++14

std::pair<int, int> p{1,2}; // OK
```

```cpp
std::pair p{1,2}; //compiler error in C++14
```

```cpp
std::pair<int, int> p{1,2}; // OK
```

```cpp
// helper to avoid specifing template params
auto p = std::make_pair(1,2);
```

```cpp
std::pair p{1,2}; //compiler error in C++14
```

```cpp
std::pair<int, int> p{1,2}; // OK
```

```cpp
// helper to avoid specifing template params
auto p = std::make_pair(1,2);
```

```cpp
// OK in C++17: first parameter is deduced to int, second to float
std::pair p{1, 2.0f};
```

```cpp
std::vector<string> vs = {"foo"s, "bar"s};          std::vector vs = {"foo"s, "bar"s};
```

```cpp
std::vector<string> vs = {"foo"s, "bar"s};
```

```cpp
std::vector vs = {"foo"s, "bar"s};
```

```cpp
std::array<std::string, 2> vs = {"foo"s, "bar"s};
```

```cpp
std::array vs = {"foo"s, "bar"s};
```

```cpp
std::vector<string> vs = {"foo"s, "bar"s};
```

```cpp
std::vector vs = {"foo"s, "bar"s};
```

```cpp
std::array<std::string, 2> vs = {"foo"s, "bar"s};
```

```cpp
std::array vs = {"foo"s, "bar"s};
```

```cpp
std::tuple<double, std::string> vs = {0.4, "bar"s};
```

```cpp
std::tuple vs = {0.4, "bar"s};
```

```cpp
std::vector<string> vs = {"foo"s, "bar"s};          std::vector vs = {"foo"s, "bar"s};

std::array<std::string, 2> vs = {"foo"s, "bar"s};   std::array vs = {"foo"s, "bar"s};

std::tuple<double, std::string> vs = {0.4, "bar"s}; std::tuple vs = {0.4, "bar"s};

std::unique_ptr<int> p{new int};                    std::unique_ptr p{new int}; // compiler error
```

unique_ptr template argument cannot be deduced because does not know whether to deduce it to be **unique_ptr<int>** or **unique_ptr<int[]>**

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

C-array vs std::array

```
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is the size of a pointer (**4** or **8** bytes depending on the architecture).

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is the size of a pointer (**4** or **8** bytes depending on the architecture).

```cpp
std::array<char, 100> x;
std::cout << sizeof(x) << '\n';
```

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is the size of a pointer (**4** or **8** bytes depending on the architecture).

```cpp
std::array<char, 100> x;
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is the size of a pointer (**4** or **8** bytes depending on the architecture).

```cpp
std::array<char, 100> x;
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(const std::array<char, 100>& x)
{
    std::cout << sizeof(x) << '\n';
}
```

C-array vs std::array

```cpp
char x[100];
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(char x[100])
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is the size of a pointer (**4** or **8** bytes depending on the architecture).

```cpp
std::array<char, 100> x;
std::cout << sizeof(x) << '\n';
```

Size of x is **100** bytes.

```cpp
void f(const std::array<char, 100>& x)
{
    std::cout << sizeof(x) << '\n';
}
```

Size of x is **100** bytes.

Algorithm predicates

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto v2 = subset(v, greaterThan5);
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto v2 = subset(v, greaterThan5);

auto greaterThan5AndLesstThan20  = [](int x) { return x > 5 && x < 20; };
auto v3 = subset(v, greaterThan5AndLessThan20);
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto v2 = subset(v, greaterThan5);

auto greaterThan5AndLesstThan20  = [](int x) { return x > 5 && x < 20; };
auto v3 = subset(v, greaterThan5AndLessThan20);

auto greaterThan5AndLesstThan20AndEven  = [](int x) { return x > 5 && x < 20 && (x % 2) == 0; };
auto v4 = subset(v, greaterThan5AndLessThan20AndEven);
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto lesstThan20  = [](int x) { return x < 20; };
auto even  = [](int x) { x % 2 == 0; };

auto v2 = subset(v, greaterThan5);
auto v3 = subset(v, [&](int x){return greaterThan5(x) && lessThan20(x);});
auto v4 = subset(v, [&](int x){return greaterThan5(x) && lessThan20(x) && even(x);});
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto lesstThan20   = [](int x) { return x < 20; };
auto even  = [](int x) { x % 2 == 0; };

auto v2 = subset(v, greaterThan5);
auto v3 = subset(v, [&](int x){return greaterThan5(x) && lessThan20(x);});
auto v4 = subset(v, [&](int x){return greaterThan5(x) && lessThan20(x) && even(x);});
auto v5 = subset(v, [&](int x){return lessThan20(x) || even(x);});
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto lesstThan20   = [](int x) { return x < 20; };
auto even  = [](int x) { x % 2 == 0; };

auto v4 = subset(v, [&](int x){return greaterThan5(x) && lessThan20(x) && even(x);});
```

```cpp
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```cpp
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto lesstThan20   = [](int x) { return x < 20; };
auto even  = [](int x) { x % 2 == 0; };

auto v4 = subset(v, And<int>(greaterThan5, lessThan20, even);
```

```
template <typename Predicate>
std::vector<int> subset(const std::vector<int>& in, Predicate&& pred)
{
    std::vector<int> out;
    std::copy_if(in.begin(), in.end(), std::back_inserter(out), pred);
    return out;
}
```

```
std::vector<int> v = {1, 2, 3, 4, 5, 6, 7, 8, 9, 18, 20, 24, 21, 55, 11};

auto greaterThan5  = [](int x) { return x > 5; };
auto lesstThan20  = [](int x) { return x < 20; };
auto even  = [](int x) { x % 2 == 0; };

auto v4 = subset(v, And<int>(greaterThan5, lessThan20, even);
```

This is more readable and explanatory than lamba syntax.

What is And<int>() ?

```cpp
struct and_
{
    template <typename T, typename Predicate, typename... Predicates>
    static bool apply(T&& t, Predicate&& pred, Predicates&&... preds)
    {
        return pred(std::forward<T>(t)) && apply(std::forward<T>(t),
                                    std::forward<Predicates>(preds)...);
    }

    template <typename T>
    static bool apply(T&& t)
    {

EXPECT_TRUE(test);

test = and_::apply(9, greaterThan5, lessThan20, even)
EXPECT_FALSE(test);
```

```cpp
struct and_
{
    template <typename T>
    static bool apply(T&& t, decltype(greaterThan5) pred1,
                             decltype(lessThan20) pred2,
                             decltype(even) pred3)
    {
        return pred1(std::forward<T>(t)) &&
               pred2(std::forward<T>(t)) &&
               apply(std::forward<T>(t), pred3);
    }

    template <typename T>
    static bool apply(T&& t, decltype(even) pred3)
    {
        return pred3(std::forward<T>(t));
    }

    template <typename T>
    static bool apply(T&& t)
    {
        return true;
    }
};
```

```cpp
struct and_
{
    template <typename T, typename Predicate, typename... Predicates>
    static bool apply(T&& t, Predicate&& pred, Predicates&&... preds)
    {
        return pred(std::forward<T>(t)) && apply(std::forward<T>(t),
                                    std::forward<Predicates>(preds)...);
    }

    template <typename T>
    static bool apply(T&& t)
    {
        return true;
    }
};
```

```cpp
bool test = and_::apply(8, greaterThan5, lessThan20, even)
EXPECT_TRUE(test);

test = and_::apply(9, greaterThan5, lessThan20, even)
EXPECT_FALSE(test);
```

```cpp
struct and_
{
    template <typename T>
    static bool apply(T&& t, decltype(greaterThan5) pred1,
                             decltype(lessThan20) pred2,
                             decltype(even) pred3)
    {
        return pred1(std::forward<T>(t)) &&
               pred2(std::forward<T>(t)) &&
               pred3(std::forward<T>(t)));
    }

    template <typename T>
    static bool apply(T&& t)
    {
        return true;
    }
};
```

```
struct and_
{
    template <typename T, typename Predicate, typename... Predicates>
    static bool apply(T&& t, Predicate&& pred, Predicates&&... preds)
    {
        return pred(std::forward<T>(t)) && apply(std::forward<T>(t),
                                    std::forward<Predicates>(preds)...);
    }

    template <typename T>
    static bool apply(T&& t)
    {
        return true;
    }
};
```

'Classic' C++11 way of "unpacking" variadic pack - use function overloading.

```
struct and_
{
    template <typename T, typename... Predicates>
    static bool apply(T&& t, Predicates&&... preds)
    {
        bool b  = true;
        int _[] = {0, b = b && preds(std::forward<T>(t))...};
        return b;
    }
};
```

Nice but cryptic trick to avoid defining 2 overloads.

```
struct and_
{
    template <typename T, typename... Predicates>
    static bool apply(T&& t, Predicates&&... preds)
    {
        return (... && preds(std::forward<T>(t)));
    }
};
```

C++17 *fold expression*

```cpp
struct and_
{
    template <typename T, typename... Predicates>
    static bool apply(T&& t, Predicates&&... preds)
    {
        return (... && preds(std::forward<T>(t)));
    }
};
```

```cpp
template <class T>
struct And
{
    std::function<bool(const T&)> f;

    template <class... Ts>
    And(Ts... ts)
    {
        f = [&ts...](const T& t) {
            return and_::apply(t, std::forward<Ts>(ts)...); };
    }

    bool operator()(const T& v) const
    {
        return f(v);
    }
};
```

```cpp
bool test = And<int>{greaterThan5, lessThan20, even}(8);
EXPECT_TRUE(test);
```

```cpp
struct and_
{
    template <typename T, typename... Predicates>
    static bool apply(T&& t, Predicates&&... preds)
    {
        return (... && preds(std::forward<T>(t)));
    }
};
```

```cpp

struct Operation
{
    std::function<bool(const T&)> f;

    template <class... Ts>
    Operation(Ts&&... ts)
    {
        f = [&ts...](const T& t) {
            return F::apply(t, std::forward<Ts>(ts)...); };
    }

    bool
    operator()(const T& v) const
    {
        return f(v);
    }
};
```

```cpp
template <typename T>
using And = Operation<T, v2::and_>;

template <typename T>
using Or = Operation<T, v2::or_>;
```

```cpp
auto v2 = subset(v, And<int>(greaterThan5, Or<int>(even, lessThan20)));
```

```
auto v2 = subset(v, And<int>(greaterThan5, Or<int>(even, lessThan20)));
```

```
auto v2 = subset(v, Or<int>(greaterThan5, even));
```

```cpp
struct Automobile
{
    std::string make;
    std::string model:
    int year;
    int horsepower;
};

std::vector<Automobile> automobiles;
```

```cpp
struct Automobile
{
    std::string make;
    std::string model:
    int year;
    int horsepower;
};

std::vector<Automobile> automobiles;
```

```cpp
struct WithMake
{
    std::string_view make;

    bool operator(const Automobile& a)
    {
        return a.make == make;
    }
};
```

```cpp
struct WithYearBetween
{
    int from;
    int to;

    bool operator(const Automobile& a)
    {
        return a.year >= from && a.year <= to;
    }
};
```

```cpp
auto oldNissans = subset(automobiles, And<Automobile>(WithMake{"Nissan"}, WithYearBetween(1990, 1995)));
```

constexpr if as SFINAE replacement

Substitution Failure Is Not An Error (SFINAE)

```cpp
struct Foo
{
    using type = int;
};

template <typename T>
void f(T t, typename T::type* p = nullptr) {}

int main()
{
    f(Foo{});
    f(20);
}
```

Substitution Failure Is Not An Error (SFINAE)

```cpp
struct Foo
{
    using type = int;
};

template <typename T>
void f(T t, typename T::type* p = nullptr) {}

int main()
{
    f(Foo{});
    f(20);
}
```

```
source>: In function 'int main()':

<source>:14:9: error: no matching function for call to 'f(int)'

    f(20);

        ^

<source>:7:6: note: candidate: 'template<class T> void f(T, typename T::type*)'

 void f(T t, typename T::type* p = nullptr) {}

      ^

<source>:7:6: note:   template argument deduction/substitution failed:

<source>: In substitution of 'template<class T> void f(T, typename T::type*) [with T = int]':

<source>:14:9:   required from here

<source>:7:6: error: 'int' is not a class, struct, or union type

Compiler returned: 1
```

Substitution Failure Is Not An Error (SFINAE)

```cpp
struct Foo
{
    using type = int;
};

template <typename T>
void f(T t, typename T::type* p = nullptr) {}

void f(...) {}

int main()
{
    f(Foo{});
    f(20);
}
```

Compiles fine thanks to SFINAE.

std::enable_if

```
template<bool B, class T = void>
struct enable_if {};

template<class T>
struct enable_if<true, T> { using type = T; }

template <typename T>
void f(T t, typename T::type* p = nullptr) {}
```

std::enable_if

```cpp
template<bool B, class T = void>
struct enable_if {};

template<class T>
struct enable_if<true, T> { using type = T; }
```

```cpp
template <typename T>
void f(T t, typename std::enable_if</*condition*/, T>::type* p = nullptr)
{
    // do something
}

template <typename T>
void f(T t, typename std::enable_if</*!condition*/, T>::type* p = nullptr)
{
    // do something else
}
```

std::enable_if

```cpp
template<bool B, class T = void>
struct enable_if {};

template<class T>
struct enable_if<true, T> { using type = T; }
```

```cpp
template <typename T>
void f(T t, typename std::enable_if<std::is_floating_point<T>::value>::type* p = nullptr)
{
    // optimized implementation for floating point types
}

template <typename T>
void f(T t, typename std::enable_if<!std::is_floating_point<T>::value>::type* p = nullptr)
{
    // default implementation for all other types
}
```

```cpp
template<class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    for (size_t i = 0; i < n; i++)
        *dest_first = *first;
}
```

```cpp
template<class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    for (size_t i = 0; i < n; i++)
        *dest_first = *first;
}
```

```cpp
struct String
{
    std::string s;
};
```
```cpp
struct SmallString
{
    char s[10];
};
```

std::vector<String>
std::vector<SmallString>

Copying a container holding contiguous memory region can be optimized by a single `memcpy` when:

Copying a container holding contiguous memory region can be optimized by a single `memcpy` when:

- container of type `T` stores data in a contiguous memory block
  - e.g. `std::vector` or `std::array`

Copying a container holding contiguous memory region can be optimized by a single `memcpy` when:

- container of type `T` stores data in a contiguous memory block
  - e.g. `std::vector` or `std::array`
- type `T` stored in the container is *trivially copyable*
  - e.g. a struct containing built-in types only

Copying a container holding contiguous memory region can be optimized by a single `memcpy` when:

- container of type T stores data in a contiguous memory block
  - e.g. `std::vector` or `std::array`

```cpp
template <class Iter>
using iterator_category = typename std::iterator_traits<Iter>::iterator_category;

template <class Iter>
struct is_random_access_iterator : std::is_same<iterator_category<Iter>,
                                                 std::random_access_iterator_tag> {};
```

- type T stored in the container is *trivially copyable*
  - e.g. a struct containing built-in types only

    for (size_t i = 0; i < n; i++)
        *dest_first = *first;
}
```

```cpp
template <class InputIt, class OutputIt>
void copy_memcpy(InputIt first, size_t n, OutputIt dest_first)
{
    memcpy(&*dest_first, &*first, n * sizeof(typename InputIt::value_type));
}
```

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first,
        std::enable_if_t<is_memcpy_copyable<InputIt>::value && is_memcpy_copyable<OutputIt>::value>* = nullptr)
{
    copy_memcpy(first, n, dest_first);
}

template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first,
        std::enable_if_t<!(is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)>* = nullptr)
{
    copy_default(first, n, dest_first);
}
```

`std::enable_if` is a powerful tool but:

- it is not easy or intuitive to use
- the code is very noisy and not easly digestable
- many conditions on types leads to explosion of number of function overloads

C++17 `if constexpr`

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

C++17 `if constexpr`

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```cpp
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
v2.resize(1);
copy_n(v1.begin(), 1, v2.begin());
```

C++17 `if constexpr`

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```cpp
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
v2.resize(1);
copy_n(v1.begin(), 1, v2.begin());
```

`copy_memcpy` is called

C++17 `if constexpr`

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```cpp
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
v2.resize(1);
copy_n(v1.begin(), 1, v2.begin());
```

copy_memcpy is called

```cpp
std::vector<String> v1 = {String{"bigger string "}};
std::vector<String> v2;
v2.resize(1);
::copy_n(v1.begin(), 1, v2.begin()); // default copy will be used
```

C++17 `if constexpr`

```
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
v2.resize(1);
copy_n(v1.begin(), 1, v2.begin());
```

copy_memcpy is called

```
std::vector<String> v1 = {String{"bigger string "}};
std::vector<String> v2;
v2.resize(1);
::copy_n(v1.begin(), 1, v2.begin()); // default copy will be used
```

copy_default is called

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```cpp
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
copy_n(v1.begin(), 1, std::back_inserter(v2));
```

```cpp
template <class InputIt, class OutputIt>
void copy_n(InputIt first, size_t n, OutputIt dest_first)
{
    if constexpr (is_memcpy_copyable<InputIt>::value &&  is_memcpy_copyable<OutputIt>::value)
    {
        copy_memcpy(first, n, dest_first);
    }
    else
    {
        copy_default(first, n, dest_first);
    }
}
```

```cpp
std::vector<SmallString> v1 = {SmallString{"small"}};
std::vector<SmallString> v2;
copy_n(v1.begin(), 1, std::back_inserter(v2));
```

copy_default is called because std::back_inserter does not return *random access iterator*

How `if constexpr` works?

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```
This is a string: Master Yoda
This is not a string: 120
```

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
template <typename T>
void print(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```
This is a string: Master Yoda
This is not a string: 120
```

```
This is a string: Master Yoda
This is not a string: 120
```

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

void print(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}
```

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

void print(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}
```

- Compiler generates two same function bodies just substituting the type
- if/else branches result in dead code

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    std::cout << "This is a string: " << t << '\n';
}

void print(const int& t)
{
    std::cout << "This is not a string: " << t << '\n';
}
```

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    std::cout << "This is a string: " << t << '\n';
}

void print(const int& t)
{
    std::cout << "This is not a string: " << t << '\n';
}
```

- Compiler generates two different function bodies with `if` or `else` branch applicable to the substituted type
- No dead code

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

void print(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}
```

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

void print(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}
```

- Compiler error: int does not have method
  `length()`

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    std::cout << "This is a string: " << t
              << " (length=" << t.length() << < ")" << '\n';
}

void print(const int& t)
{
    std::cout << "This is not a string: " << t << '\n';
}
```

What the compiler generates?

```cpp
template <typename T>
void print(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        std::cout << "This is a string: " << t
                  << " (length=" << t.length() << < ")" << '\n';
    }
    else
    {
        std::cout << "This is not a string: " << t << '\n';
    }
}

print(std::string{"Master Yoda"});
print(120);
```

```cpp
void print(const std::string& t)
{
    std::cout << "This is a string: " << t
              << " (length=" << t.length() << < ")" << '\n';
}

void print(const int& t)
{
    std::cout << "This is not a string: " << t << '\n';
}
```

- Compiles correctly because call to `length()` in only generated in the function with `string` substitution.

Return type deduction

- C++14 standard introduced return type deduction

```cpp
auto abs(int x)
{
return x < 0 ? -x : x;
}
```

Return type deduction

- C++14 standard introduced return type deduction

```
auto abs(int x)
{
return x < 0 ? -x : x;
}
```

- This feature should not be overused because it may make the code less readable

Return type deduction

- C++14 standard introduced return type deduction

```cpp
auto abs(int x)
{
return x < 0 ? -x : x;
}
```

- This feature should not be overused because it may make the code less readable

- However, combined with `if constexpr` it brings additional capabilities to generic programming

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

```cpp
auto makeFooOrBar(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto makeFooOrBar(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}
```

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

```cpp
auto makeFooOrBar(const std::string& t)
{
    if (std::is_same_v<std::string, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto makeFooOrBar(const int& t)
{
    if (std::is_same_v<int, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}
```

- Compiler error: cannot deduce type.

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

```cpp
auto makeFooOrBar(const std::string& t)
{
    return Foo{};
}

auto makeFooOrBar(const int& t)
{
    return Bar{};
}
```

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

```cpp
auto makeFooOrBar(const std::string& t)
{
    return Foo{};
}

auto makeFooOrBar(const int& t)
{
    return Bar{};
}
```

```cpp
std::cout << "Am I Foo?: "
          << std::is_same_v<Foo, decltype(fooOrBar1)> << '\n';
std::cout << "Am I Foo?: "
          << std::is_same_v<Foo, decltype(fooOrBar2)> << '\n';
```

```
Am I Foo: 1
Am I Foo: 0
```

What the compiler generates?

```cpp
struct Foo{};
struct Bar{};

template <typename T>
auto makeFooOrBar(const T& t)
{
    if constexpr (std::is_same_v<T, std::string>)
    {
        return Foo{};
    }
    else
    {
        return Bar{};
    }
}

auto fooOrBar1 = makeFooOrBar("Foo or Bar");
auto fooOrBar2 = makeFooOrBar(120);
```

```cpp
auto makeFooOrBar(const std::string& t)
{
    return Foo{};
}

auto makeFooOrBar(const int& t)
{
    return Bar{};
}
```

```cpp
std::cout << "Am I Foo?: "
          << std::is_same_v<Foo, decltype(fooOrBar1)> << '\n';
std::cout << "Am I Foo?: "
          << std::is_same_v<Foo, decltype(fooOrBar2)> << '\n';
```

```
Am I Foo: 1
Am I Foo: 0
```

We can have compile functions which return **different** types based on input type

Small buffer optimization

We need to write a Buffer class with compile-time size which:

- is iterable
- uses dynamic memory allocation only if the size is greater than 1024B

```cpp
template <size_t N>
struct DynamicBuffer : private std::vector<std::byte>
{
    using Base = std::vector<std::byte>;

    DynamicBuffer() : Base{N} {}

    using Base::begin;
    using Base::end;
    using Base::size;
};
```

```cpp
template <size_t N>
struct StaticBuffer : private std::array<std::byte, N>
{
    using Base = std::array<std::byte, N>;

    using Base::begin;
    using Base::end;
    using Base::size;
};
```

```cpp
template <size_t N>                          template <size_t N>
struct DynamicBuffer : private std::vector<std::byte>    struct StaticBuffer : private std::array<std::byte, N>
{                                            {
    using Base = std::vector<std::byte>;         using Base = std::array<std::byte, N>;

    DynamicBuffer() : Base{N} {}

    using Base::begin;                           using Base::begin;
    using Base::end;                             using Base::end;
    using Base::size;                            using Base::size;
};                                           };
```

What we need is a single class that covers both cases:

```
template <size_t N>                                template <size_t N>
struct DynamicBuffer : private std::vector<std::byte>    struct StaticBuffer : private std::array<std::byte, N>
{                                                  {
    using Base = std::vector<std::byte>;               using Base = std::array<std::byte, N>;

    DynamicBuffer() : Base{N} {}

    using Base::begin;                                 using Base::begin;
    using Base::end;                                   using Base::end;
    using Base::size;                                  using Base::size;
};                                                 };
```

What we need is a single class that covers both cases:

```
template <size_t N>
struct Buffer : private /* array or vector */
{
    using Base = /* array or vector */

    /*...*/

    using Base::begin;
    using Base::end;
    using Base::size;
};
```

```cpp
template <size_t N>
constexpr auto make_base()
{
    if constexpr (N > 1024)
    {
        return std::vector<std::byte>(N);
    }
    else
    {
        return std::array<std::byte, N>();
    }
}
```

```cpp
template <size_t N>
constexpr auto make_base()
{
    if constexpr (N > 1024)
    {
        return std::vector<std::byte>(N);
    }
    else
    {
        return std::array<std::byte, N>();
    }
}
```

```cpp
template <size_t N>
struct Buffer : private decltype(make_base<N>())
{
    using Base = decltype(make_base<N>());

    Buffer() : Base(make_base<N>()) {}

    using Base::begin;
    using Base::end;
    using Base::size;
};
```

```cpp
template <size_t N>
constexpr auto make_base()
{
    if constexpr (N > 1024)
    {
        return std::vector<std::byte>(N);
    }
    else
    {
        return std::array<std::byte, N>();
    }
}
```

```cpp
template <size_t N>
struct Buffer : private decltype(make_base<N>())
{
    using Base = decltype(make_base<N>());

    Buffer() : Base(make_base<N>()) {}

    using Base::begin;
    using Base::end;
    using Base::size;
};
```

```cpp
Buffer<256> smallBuff; // stack
Buffer<2048> bigBuff;  // heap
```

JSON serialization library in 10 minutes

```cpp
void print(int v)
{
    std::cout << v;
}
```

- Prints integer.

```cpp
void print(int v)
{
    std::cout << v;
}
```

- Prints integer.

```cpp
void print(double v)
{
    std::cout << v;
}
```

- Prints double.

```
void print(int v)
{
    std::cout << v;
}
```

- Prints integer.

```
void print(double v)
{
    std::cout << v;
}
```

- Prints double.

```
void print(const std::string& v)
{
    std::cout << v;
}
```

- Prints string.

```cpp
void print(int v)
{
    std::cout << v;
}
```

- Prints integer.

```cpp
void print(double v)
{
    std::cout << v;
}
```

- Prints double.

```cpp
void print(const std::string& v)
{
    std::cout << v;
}
```

- Prints string.

```cpp
template <typename T>
void print(const T& v)
{
    std::cout << v;
}
```

- Prints any type `T` for which `operator<<` is defined.

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    if (!n.empty())
    {
        std::cout << '\"' << n << '\"' << ':';
    }
    std::cout << v;
}
```

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    if (!n.empty())
    {
        std::cout << '\"' << n << '\"' << ':';
    }
    std::cout << v;
}
```

```cpp
template <typename T>
void println(const T& v, std::string_view n = {})
{
    print(v, n);
    std::cout << '\n';
}
```

```
template <typename T>
void print(const T& v, std::string_view n = {})
{
    if (!n.empty())
    {
        std::cout << '\"' << n << '\"' << ':';
    }
    std::cout << v;
}
```

```
template <typename T>
void println(const T& v, std::string_view n = {})
{
    print(v, n);
    std::cout << '\n';
}
```

```
println(123, "x");                    "x":123
println(0.4, "x");                    "x":0.4
println("Print me", "x");             "x":Print me
println(true, "x");                   "x":1
```

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    if (!n.empty())
    {
        std::cout << '\"' << n << '\"' << ':';
    }
    std::cout << v;
}
```

```cpp
template <typename T>
void println(const T& v, std::string_view n = {})
{
    print(v, n);
    std::cout << '\n';
}
```

println(123, "x");
println(0.4, "x");
println("Print me", "x");
println(true, "x");
```

```
"x":123
"x":0.4
"x":Print me
"x":1
```

```cpp
std::vector v = {1,2,3};
println(v, "numbers");
```

```
error: invalid operands to binary expression ('std::__1::ostream' (aka 'basic_
    std::__1::allocator<int> >')
std::cout << v << '\n';
~~~~~~~~~ ^  ~
```

```cpp
template <typename T>
void print_default(const T& v)
{
    std::cout << v << '\n';
}
```

- Prints any type T for which operator<< is defined.

```cpp
template <typename T>
void print_default(const T& v)
{
    std::cout << v << '\n';
}
```

- Prints any type T for which `operator<<` is defined.

```cpp
template <typename T>
void print_container(const T& v)
{
    std::cout << '[';
    for (const auto& x : v)
    {
        print(x, {});
        std::cout << ",";
    }
    std::cout << '\b' << ']';
}
```

- Prints any type T :
  - which is *iterable* and
  - `T::operator*` returns type for which `operator<<` is defined

```cpp
template <typename T>
void print_default(const T& v)
{
    std::cout << v << '\n';
}
```

- Prints any type T for which `operator<<` is defined.

```cpp
template <typename T>
void print_container(const T& v)
{
    std::cout << '[';
    for (const auto& x : v)
    {

    }
    else
    {
        print_default(v);
    }
}
```

- Prints any type T for which `operator<<` is defined.
- Prints any type T :
  - which is *iterable* and
  - `T::operator*` returns type for which `operator<<` is defined

What are the properties (traits) of a container?

What are the properties (traits) of a container?

- `begin()` and `end()` member functions

What are the properties (traits) of a container?

- `begin()` and `end()` member functions
- `iterator` member type

Detect member function existance at compile-time (C++14)

```cpp
template <typename T>
struct has_member_function_begin
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().begin(),
                                            std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

```cpp
template <typename T>
struct has_member_function_begin
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().begin(),
                                            std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

```cpp
std::cout << "has begin: " << has_member_function_begin<int>::value;              has begin: 0
std::cout << "has begin: " << has_member_function_begin<std::vector<int>>::value;  has begin: 1
std::cout << "has begin: " << has_member_function_begin<std::map<int, int>>::value; has begin: 1
```

Test if a class is a container

```cpp
template <typename T>
struct has_member_function_begin
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().begin(),
                                           std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

Test if a class is a container

```cpp
template <typename T>
struct has_member_function_begin
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().begin(),
                                           std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

```cpp
template <typename T>
struct has_member_function_end
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().end(),
                                           std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

Test if a class is a container

```cpp
template <typename T>
struct has_member_function_begin
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().begin(),
                                            std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

```cpp
template <typename T>
struct has_member_function_end
{
    template <typename U>
    static auto apply(void* p) -> decltype(std::declval<U>().end(),
                                           std::true_type{});

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

```cpp
template <typename T>
struct has_member_type_iterator
{
    template <typename U>
    static auto apply(typename U::iterator* p) -> std::true_type

    template <typename>
    static auto apply(...) -> std::false_type;

    static constexpr bool value = decltype(apply<T>(nullptr))::value;
};
```

Test if a class is a container

```cpp
template <typename T>
struct is_container : std::integral_constant<bool, has_member_function_begin<T>::value &&
                                                   has_member_function_end<T>::value &&
                                                   has_member_type_iterator<T>::value;

{
};
```

Test if a class is a container

```cpp
template <typename T>
struct is_container : std::integral_constant<bool, has_member_function_begin<T>::value &&
                                                   has_member_function_end<T>::value &&
                                                   has_member_type_iterator<T>::value;

{
};
```

```cpp
std::cout << "is_container: " << is_container<int>::value;              is_container: 0
std::cout << "is_container: " << is_container<std::vector<int>>::value;  is_container: 1
std::cout << "is_container: " << is_container<std::map<int, int>>::value; is_container: 1
```

std::void_t

```
template <typename...>
using void_t = void;
```

std::void_t

```
template <typename...>
using void_t = void;
```

```
using T = std::void_t<int>; // T is void
using U = std::void_t<int, std::string, double>; // U is also void
```

Test if a class is a container with `std::void_t`

```cpp
template <typename T, typename=void>
struct is_container : std::false_type{};

template <typename T>
struct is_container<T, std::void_t<decltype(std::declval<T>().begin()),
                                   decltype(std::declval<T>().end()),
                                   typename T::iterator>> : std::true_type{};
```

```cpp
template <typename T, typename=void>
struct is_container : std::false_type{};

template <typename T>
struct is_container<T, std::void_t<decltype(std::declval<T>().begin()),
                                   decltype(std::declval<T>().end()),
                                   typename T::iterator>> : std::true_type{};
```

```cpp
std::cout << "is_container: " << is_container<int>::value;              is_container: 0

void print_container(const T& v)a {/*...*/}

template <typename T>
void print_pointer(const T& v)
{
    if (v == nullptr)
        std::cout << "null";
    else
        print(*v, {});
}
```

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    /*...*/

    if constexpr (is_container<T>::value &&
                  !std::is_convertible_v<T, std::string>)
    {
        print_container(v);
    }
    else if constexpr (std::is_pointer<T>::value ||
                       is_pointer_like<T>::value)
    {
        print_pointer(v);
    }
    else
    {
        print_default(v);
    }
}
```

```cpp
println(123, "x");
println(0.4, "x");
println("Print me", "x");

std::vector<int> v = {1,2,3};
println(v, "numbers");

int* x = new int(5);
int* y = nullptr;
println(x, "x");
println(y, "y");

auto u = std::make_unique<int>(765);
println(u, "u");
```

```
"x":123
"x":0.4
"x":Print me

"numbers":[1,2,3]

"x"=5
"y"=null

"u"=765
```

```cpp
template <typename T>
void print_default(const T& v) {/*...*/}

template <typename T>
void print_container(const T& v)a {/*...*/}

template <typename T>
void print_pointer(const T& v)
{
    if (v == nullptr)
        std::cout << "null";
    else
        print(*v, {});
}
```

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    /*...*/

    if constexpr (is_container<T>::value &&
                  !std::is_convertible_v<T, std::string>)
    {
        print_container(v);
    }
    else if constexpr (std::is_pointer<T>::value ||
                       is_pointer_like<T>::value)
    {
        print_pointer(v);
    }
    else
    {
        print_default(v);
    }
}
```

```cpp
println(123, "x");
println(0.4, "x");
println("Print me", "x");

std::vector<int> v = {1,2,3};
println(v, "numbers");

int* x = new int(5);
int* y = nullptr;
println(x, "x");
println(y, "y");

auto u = std::make_unique<int>(765);
println(u, "u");
auto s = std::make_shared<int>(54);
println(s, "s");
```

```
"x":123
"x":0.4
"x":Print me

"numbers":[1,2,3]

"x":5
"y":null

"u":765

"s":54
```

std::optional

std::optional

std::optional is pointer-like so will fall into print_pointer:

```cpp
template <typename T>
void print_pointer(const T& v)
{
    if (v == nullptr)
        std::cout << "null";
    else
        print(*v, {});
}
```

std::optional

std::optional is pointer-like so will fall into `print_pointer`:

```cpp
template <typename T>
void print_pointer(const T& v)
{
    if (v == nullptr)
        std::cout << "null";
    else
        print(*v, {});
}
```

Won't compile because `std::optional` is not comparable with nullptr

std::optional

```cpp
template <typename T>
auto makeNullValue()
{
    if constexpr (std::is_assignable_v<T, std::nullopt_t>)
    {
        return std::nullopt;
    }
    else
    {
        return nullptr;
    }
}
```

```cpp
template <typename T>
void print_pointer(const T& v)
{
    if (v == makeNullValue())
        std::cout << "null";
    else
        print(*v, {});
}
```

Now `print_pointer` works for:

- raw pointer
- smart pointers
- `std::optional`
- any pointer-like user type whose empty value is either `nullptr` or `std::nullopt`

```cpp
println(123, "x");
println(0.4, "x");
println("Print me", "x");

std::vector<int> v = {1,2,3};
println(v, "numbers");

int* x = new int(5);
int* y = nullptr;
println(x, "x");
println(y, "y");

auto u = std::make_unique<int>(765);
println(u, "u");
auto s = std::make_shared<int>(54);
println(s, "s");

std::optional<int> o1 = 111;
std::optional<int> o2;
println(o1, "o1");
println(o2, "o2");
```

```
"x":123
"x":0.4
"x":Print me

"numbers":[1,2,3]

"x":5
"y":null

"u":765

"s":54

"o1":111
"o2":null
```

```cpp
std::vector<std::optional<int>> vo = {4,5,6, std::nullopt, 8};
println(vo, "vector_of_optionals");
```

```
vector_of_optionals=[4,5,6,null,8]
```

```
std::vector<std::optional<int>> vo = {4,5,6, std::nullopt, 8};
println(vo, "vector_of_optionals");
```

vector_of_optionals=[4,5,6,null,8]

```
std::optional<std::vector<std::optional<int>>> ovo = {{4,5,6, std::nullopt, 8}};
println(ovo, "optional_vector_of_optionals");
```

optional_vector_of_optionals=[4,5,6,null,8]

```
std::vector<std::optional<int>> vo = {4,5,6, std::nullopt, 8};
println(vo, "vector_of_optionals");
```
```
vector_of_optionals=[4,5,6,null,8]
```

```
std::optional<std::vector<std::optional<int>>> ovo = {{4,5,6, std::nullopt, 8}};
println(ovo, "optional_vector_of_optionals");
```
```
optional_vector_of_optionals=[4,5,6,null,8]
```

vector of optional works out of the box

```cpp
std::vector<std::optional<int>> vo = {4,5,6, std::nullopt, 8};
println(vo, "vector_of_optionals");

std::optional<std::vector<std::optional<int>>> ovo = {{4,5,6, std::nullopt, 8}};
println(ovo, "optional_vector_of_optionals");
```

```
vector_of_optionals=[4,5,6,null,8]

optional_vector_of_optionals=[4,5,6,null,8]
```

vector of optional works out of the box

```cpp
template <typename T>
void print_default(const T& v) {/*...*/}

template <typename T>
void print_container(const T& v)
{
    std::cout << '[';
    for (const auto& x : v)
    {
        print(x, {});
        std::cout << ",";
    }
    std::cout << '\b' << ']';
}

template <typename T>
void print_pointer(const T& v)
{
    if (v == nullptr)
        std::cout << "null";
    else
        print(*v, {});
}
```

```cpp
template <typename T>
void print(const T& v, std::string_view n = {})
{
    /*...*/

    if constexpr (is_container<T>::value &&
                  !std::is_convertible_v<T, std::string>)
    {
        print_container(v);
    }
    else if constexpr (std::is_pointer<T>::value ||
                       is_pointer_like<T>::value)
    {
        print_pointer(v);
    }
    else
    {
        print_default(v);
    }
}
```

So, thus far we can print:

- primitive types
- string
- containers
- pointers
- optional
- any composition of the above

So, thus far we can print:

- primitive types
- string
- containers
- pointers
- optional
- any composition of the above

Let's make it a serialization library...

```cpp
template <typename T>
void print_default(const T& v)
{
    std::cout << v;
}
```

```
template <typename T>
void print_default(const T& v)
{
    std::cout << v;
}
```

```
template <typename T>
void print_default(std::ostream& os, const T& v)
{
    os << v;
}
```

```cpp
template <typename T>
void print_default(const T& v);

template <typename T>
void print_container(const T& v);

template <typename T>
void print_pointer(const T& v);

template <typename T>
void print(const T& v, std::string_view n);

template <typename T>
void println(const T& v, std::string_view n);
```

```cpp
template <typename T>
void print_default(const T& v);

template <typename T>
void print_container(const T& v);

template <typename T>
void print_pointer(const T& v);

template <typename T>
void print(const T& v, std::string_view n);

template <typename T>
void println(const T& v, std::string_view n);
```

```cpp
template <typename T>
void print_default(std::ostream& os, const T& v);

template <typename T>
void print_container(std::ostream& os, const T& v);

template <typename T>
void print_pointer(std::ostream& os, const T& v);

template <typename T>
void print(std::ostream& os, const T& v, std::string_view n);

template <typename T>
void println(std::ostream& os, const T& v, std::string_view n);
```

```cpp
class Writer
{
    std::ostream& mOs;
public:
    Writer(std::ostream& os) : mOs(os) {}

    template <typename T>
    friend Writer& operator<<(Writer& writer, Nvp<T> nvp)
    {
        print(writer.mOs, nvp.second, nvp.first);
        return writer;
    }

    template <typename T>
    friend Writer& operator<<(Writer& writer, const T& v)
    {
        print(writer.mOs, v);
        return writer;
    }
};
```

```cpp
template <typename T>
using Nvp = std::pair<std::string_view, const T&>;

template <typename T>
Nvp<T> makeNvp(std::string_view n, const T& v)
{
    return std::make_pair(n, std::cref(v));
}
```

```cpp
template <typename T>
void print(std::ostream& os, const T& v, std::string_view n)
{ /*...*/}
```

```cpp
Writer writer(std::cout);

writer << makeNvp("x", 123) << '\n';                                    "x":123
writer << makeNvp("x", 0.4) << '\n';                                    "x":0.4

writer << makeNvp("optioal_vector_of_optionals", ovo) << '\n';       "optioal_vector_of_optionals":[4,5,6,null,8]
```

```cpp
Writer writer(std::cout);

writer << makeNvp("x", "Print me") << '\n';                          "x":Print me
```

```cpp
template <typename T>
void print_default(std::ostream& os, const T& v)
{
    os << v;
}
```

```
Writer writer(std::cout);

writer << makeNvp("x", "Print me") << '\n';                    "x":"Print me"
```

```cpp
template <typename T>
void print_default(std::ostream& os, const T& v)
{
    if constexpr (std::is_convertible_v<T, std::string_view>)
    {
        os << '\"' << v << '\"';
    }
    else
    {
        os << v;
    }
}
```

```cpp
Writer writer(std::cout);

writer << makeNvp("b", "true") << '\n';                                    "b":1
```

```cpp
template <typename T>
void print_default(std::ostream& os, const T& v)
{
    if constexpr (std::is_convertible_v<T, std::string_view>)
    {
        os << '\"' << v << '\"';
    }
    else
    {
        os << v;
    }
}
```

```
Writer writer(std::cout);

writer << makeNvp("b", "true") << '\n';                                    "b":true
```

```cpp
template <typename T>
void print_default(std::ostream& os, const T& v)
{
    if constexpr (std::is_convertible_v<T, std::string_view>)
    {
        os << '\"' << v << '\"';
    }
    else
    {
        os << v;
    }
}

void print_default(std::ostream& os, bool v)
{
    os << std::boolalpha << v << std::noboolalpha;
}
```

User types

```cpp
struct Foo
{
    std::string s;
    int i;
};
```

User types

```cpp
struct Foo
{
    std::string s;
    int i;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("i", i) << ',' << makeNvp("s", s);
    }
};
```

User types

```cpp
struct Foo
{
    std::string s;
    int i;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("i", i) << ',' << makeNvp("s", s);
    }
};
```

```cpp
template <typename T>
void
print(std::ostream& os, const T& v, std::string_view n)
{
    if (!n.empty())
    {
        std::cout << '\"' << n << '\"' << ':';
    }

    if constexpr (is_container<T>::value &&
                  !std::is_convertible_v<T, std::string>)
    {
        print_container(os, v);
    }
    else if constexpr (is_pointer_like<T>::value || std::is_pointer_v<T>)
    {
        print_pointer(os, v);
    }
    else if constexpr (has_member_function_serialize<T, Writer&>::value)
    {
        Writer writer{os};
        writer << '{';
        v.serialize(writer);
        writer << '}';
    }
    else
    {
        print_default(os, v);
    }
}
```

```cpp
template <typename T, class Writer, typename = void>
struct has_member_function_serialize : std::false_type {};

template <typename T, class Writer>
struct has_member_function_serialize<T, Writer,
    std::void_t<decltype(std::declval<T>().serialize(std::declval<Writer>()))>>
        : std::true_type {};
```

```cpp
struct Foo
{
    int i;
    std::string s;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("i", i) << ',' << makeNvp("s", s);
    }
};

struct Bar
{
    std::vector<Foo> foos;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("foos", foos);
    }
};

struct Baz
{
    std::string name;
    bool valid;
    std::optional<Bar> bar;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("name", name) << ','
               << makeNvp("valid", valid) << ','
               << makeNvp("bar", bar);
    }
};
```

```cpp
Writer writer(std::cout);

Bar bar{{Foo{10, "foo10"}, Foo{20, "foo20"}}};
Baz baz{"Some cool BAZ", true, bar};
writer << makeNvp("baz", baz) << '\n';
```

```cpp
struct Foo
{
    int i;
    std::string s;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("i", i) << ',' << makeNvp("s", s);
    }
};

struct Bar
{
    std::vector<Foo> foos;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("foos", foos);
    }
};

struct Baz
{
    std::string name;
    bool valid;
    std::optional<Bar> bar;

    template <class Writer>
    void serialize(Writer& writer) const
    {
        writer << makeNvp("name", name) << ','
               << makeNvp("valid", valid) << ','
               << makeNvp("bar", bar);
    }
};
```

```cpp
Writer writer(std::cout);

Bar bar{{Foo{10, "foo10"}, Foo{20, "foo20"}}};
Baz baz{"Some cool BAZ", true, bar};
writer << makeNvp("baz", baz) << '\n';
```

```
{"name":"Some cool BAZ","valid":true,"bar":{"foos":[{"i":10,"s":"foo10"},{"i":20,"s":"foo20"}]}}
```

Thank you.
